GAN-balanced plant disease classification ↗

Does generating minority-class images fix an imbalanced dataset?

A GAN generates extra leaf images for the under-represented classes of a 38-class plant disease dataset. A custom CNN is then trained on the balanced set and checked with 5-fold cross-validation.

ACCURACY	MACRO F1	CLASSES

HIGGS: logistic regression vs neural network [↗](#)

How much does model capacity matter at 11 million samples?

Both models were trained on 16 slices of the HIGGS collision dataset (11M events, 28 features), from 1% to 100%, to find where extra data stops paying off. The network's accuracy is already 76.6% at 30% of the data and only reaches 76.8% at 100%.
